Hermite Interpolation

Summary and Review of Polynomial Interpolation

Implement Hermite interpolation with double nodes, using divided differences.

Applications

1. Consider the function $f : (-1, \infty) \rightarrow \mathbb{R}$, $f(x) = \frac{1}{1+x}$ and the nodes $x_0 = 0, x_1 = 1$ and $x_2 = 2$. Plot on the same set of axes the Lagrange and the Hermite (with double nodes) polynomials that interpolate the data. What are the degrees of the two polynomials?
2. The data below refers to a moving object.

Time	0	3	5	8	13
Distance	0	225	383	623	993
Velocity	0	77	80	74	72

Use interpolation to approximate the position and the speed of the object at time $t = 10$.

Optional

3. Approximate $\sqrt[3]{7}$ using Hermite interpolation with 4 double nodes.

Review of Polynomial Interpolation

I. Summary

1. What **type** of interpolation? It depends on what information is given:

- **only** values of the function are given, e.g. $f(-1), f(0), f(1) \rightarrow$ **Lagrange**
- values of the function are known for **all** nodes and, in addition, for some nodes, **all the derivatives up to some order (not the same for all nodes)** are also given, e.g. $f(-1), f(0), f'(0), f''(0), f(1), f'(1) \rightarrow$ **Hermite**
- **random** values of the **function and/or of the derivatives** are given, e.g. $f(-1), f'(0), f''(0), f'(1), f'''(2) \rightarrow$ **Birkhoff**

2. What **computational formula** is more convenient?

- Lagrange \rightarrow **Newton's divided (/forward/backward) differences** or Aitken's algorithm
- Hermite \rightarrow **Newton's divided differences** (**caution!!**, for multiple nodes, divided differences are computed with *derivatives*)
- Birkhoff \rightarrow **fundamental (basis) polynomials or directly** (determine the coefficients of the polynomial from the interpolation conditions)

3. The **degree** of the interpolation polynomial

- the **set of indices** I_k consists of the **orders** of the derivatives that are given for each node x_k (the derivative of order 0 is the function itself), e.g.

$$\begin{aligned}x_0 &= -1 \text{ and we know } f(-1), f'(-1) \rightarrow I_0 = \{0, 1\} \\x_1 &= 0 \text{ and we know } f'(0), f''(0) \rightarrow I_1 = \{1, 2\} \\x_2 &= 1 \text{ and we know } f(1), f'''(1), f^{(iv)}(1) \rightarrow I_2 = \{0, 3, 4\} \\x_3 &= 2 \text{ and we know } f''(2), f^{(v)}(2) \rightarrow I_3 = \{2, 5\}\end{aligned}$$

- the **degree** of the interpolation polynomial with nodes x_0, \dots, x_m is

$$n = |I_0| + \dots + |I_m| - 1,$$

where $|A| = \text{card}(A)$ is the number of elements of the set A .

4. Birkhoff interpolation

- The **notation** for **Birkhoff fundamental polynomials**: b_{ij} , where i is the index of the **node**, j is the **order of the derivative** that is known for that node, e.g. if we are given

$$f'(-1), f'(0), f''(0), f(1), f''(1),$$

that means

- $f'(-1)$: for node $x_0 = -1$, the **first** derivative is known $\rightarrow b_{01}$
- $f'(0), f''(0)$: for node $x_1 = 0$, the **first** and **second** derivatives are given $\rightarrow b_{11}, b_{12}$

- $f(1)$, $f''(1)$: for node $x_2 = 1$, the **zero** and **second** derivatives are given $\rightarrow b_{20}$, b_{22} .
So the fundamental polynomials are

$$b_{01}, b_{11}, b_{12}, b_{20}, b_{22}$$

and the pairs of indices used are

$$(0, 1), (1, 1), (1, 2), (2, 0), (2, 2). (*)$$

- The **interpolation polynomial** is then the **linear combination** of the basis polynomials found above, each having as coefficient the value of the function/derivative that it corresponds to:

$$(Bf)(x) = b_{01}f'(-1) + b_{11}f'(0) + b_{12}f''(0) + b_{20}f(1) + b_{22}f''(1).$$

- Each basis polynomial b_{ij} has (at most) **the same degree** as the overall interpolation polynomial Bf (discussed above) and its coefficients are determined from the conditions

$$b_{ij}^{(j)}(x_i) = 1,$$

while at **all other combinations of indices used in the writing of the polynomial**, it is 0. For the example above (check (*)):

$$\left\{ \begin{array}{l} (0, 1) \rightarrow b_{01}'(x_0) = 1 \\ (1, 1) \rightarrow b_{01}'(x_1) = 0 \\ (1, 2) \rightarrow b_{01}''(x_1) = 0 \\ (2, 0) \rightarrow b_{01}(x_2) = 0 \\ (2, 2) \rightarrow b_{01}''(x_2) = 0 \end{array} \right\}, \left\{ \begin{array}{l} (0, 1) \rightarrow b_{11}'(x_0) = 0 \\ (1, 1) \rightarrow b_{11}'(x_1) = 1 \\ (1, 2) \rightarrow b_{11}''(x_1) = 0 \\ (2, 0) \rightarrow b_{11}(x_2) = 0 \\ (2, 2) \rightarrow b_{11}''(x_2) = 0 \end{array} \right\}, \left\{ \begin{array}{l} (0, 1) \rightarrow b_{12}'(x_0) = 0 \\ (1, 1) \rightarrow b_{12}'(x_1) = 0 \\ (1, 2) \rightarrow b_{12}''(x_1) = 1 \\ (2, 0) \rightarrow b_{12}(x_2) = 0 \\ (2, 2) \rightarrow b_{12}''(x_2) = 0 \end{array} \right\},$$

and so on.

- If finding the Birkhoff polynomial **directly**, just impose the interpolation conditions on Bf (after determining its degree **correctly**!). There is just one system in this case, but it is, in general, **more difficult** to solve than the systems for b_{ij} and the remainder is more difficult to find.
5. **Check** at the end that the polynomial found **satisfies** the interpolation conditions. If it exists, the interpolating polynomial is **unique**.

II. Peano's Theorem for the Remainder

- We have an approximating formula

$$\begin{aligned} f(x) &\approx (P_n f)(x), \text{ or} \\ f(x) &= (P_n f)(x) + (R_n(f))(x), \text{ for } x \in [a, b], \end{aligned}$$

where $[a, b]$ is the smallest interval containing all the interpolation nodes. The formula has **degree of precision (or exactness)** $d = n$, if it is **exact** for **all** polynomials of degree up to n , i.e.

$$\begin{aligned} f(x) &= (P_n f)(x), \text{ for } f(x) = e_k(x) = x^k, \quad k = 0, 1, \dots, n, \\ e_{n+1}(x) &\neq (P_n e_{n+1})(x), \text{ or, equivalently, } R_n(e_{n+1}) \neq 0. \end{aligned}$$

- The remainder has the form

$$(R_n(f))(x) = \int_a^b K_n(x, t) f^{(n+1)}(t) dt$$

where

$$K_n(x, t) = R_n\left(\frac{(x-t)_+^n}{n!}\right) = \frac{1}{n!} R_n((x-t)_+^n) = \frac{1}{n!} ((x-t)_+^n - P_n((x-t)_+^n)),$$

$$(x-t)_+^n = ((x-t)_+)^n = \begin{cases} (x-t)^n, & x \geq t \\ 0, & x < t \end{cases}.$$

- If K has constant sign on $[a, b]$, then (by the MVT)

$$(R_n(f))(x) = \frac{f^{(n+1)}(\xi)}{(n+1)!} R_n(e_{n+1})(x), \quad \xi \in [a, b].$$

- The function $F(x) = (x-t)_+^n$ has the **derivative**

$$F'(x) = \frac{\partial[(x-t)_+^n]}{\partial x} = n(x-t)_+^{n-1}$$

and the **integral** (this will only be needed later on, in Chapter 4)

$$\int_a^b F(x) dx = \frac{1}{n+1} (x-t)_+^{n+1} \Big|_{x=a}^{x=b} = \frac{1}{n+1} [(b-t)_+^{n+1} - (a-t)_+^{n+1}]$$

- Peano's theorem can also be used to derive remainder formulas for Lagrange or Hermite interpolation, but we already have other forms for those (recall that Peano's theorem refers to *any* linear functional).

III. Practice Problems

Find the polynomial of minimum degree that interpolates the given data. Determine the remainder for each approximation.

1. $f(0), f(1/2), f(1)$; **Answer:**

$$L_2 f(x) = (2x-1)(x-1)f(0) + 4x(1-x)f(1/2) + x(2x-1)f(1),$$

$$R_2 f(x) = \frac{x(x-1/2)(x-1)}{3!} f'''(\xi), \quad \xi \in (0, 1).$$

2. $f(-1), f(0), f'(0), f(1)$; **Answer:**

$$H_3 f(x) = \frac{1}{2} x^2 (1-x) f(-1) + (1-x^2) f(0) + x(1-x^2) f'(0) + \frac{1}{2} x^2 (x+1) f(1),$$

$$R_3 f(x) = \frac{x^2(x^2-1)}{4!} f^{(iv)}(\xi), \quad \xi \in (-1, 1).$$

3. $f(0), f'(0), f'(1)$. **Answer:**

$$B_2 f(x) = f(0) + \frac{1}{2} x(2-x) f'(0) + \frac{1}{2} x^2 f'(1),$$

$$R_2 f(x) = \frac{2x^3 - 3x^2}{2 \cdot 3!} f'''(\xi), \quad \xi \in (0, 1).$$
